## SUMMARY SPECIFICATION

### KODAK KAI-1020 IMAGE SENSOR

1000 (H) X 1000 (V) PROGRESSIVE SCAN INTERLINE CCD IMAGE SENSOR

#### DESCRIPTION

The KODAK KAI-1020 Image Sensor is a one megapixel interline CCD with integrated clock drivers and on-chip correlated double sampling. The progressive scan architecture and global electronic shutter provide excellent image quality for full motion video and still image capture.

The integrated clock drivers allow for easy integration with CMOS logic timing generators. The sensor features a fast line dump for high-speed sub-window readout and single (30 fps) or dual (48 fps) output operation.

#### FEATURES

- 10 bits dynamic range at 40 MHz
- Large 7.4  $\mu\text{m}$  square pixels for high sensitivity
- Progressive scan (non-interlaced)
- Integrated vertical clock drivers
- Integrated correlated double sampling (CDS) up to 40 MHz
- Integrated electronic shutter driver
- Reversible HCCD capable of 40MHz operation All timing inputs 0 to 5 Volts
- Single or dual video output operation
- Progressive scan or interlaced
- Fast dump gate for high speed sub-window readout
- Antiblooming protection

#### APPLICATIONS

- Industrial Imaging
- Medical Imaging

Parameter	Typical Value
Architecture	Interline CCD, Progressive Scan
Total Number of Pixels	1028 (H) x 1008 (V)
Number of Effective Pixels	1004 (H) x 1004 (V)
Number of Active Pixels	1000 (H) x 1000 (V)
Pixel Size	7.4 $\mu\text{m}$ (H) x 7.4 $\mu\text{m}$ (V)
Active Image Size	7.4 mm (H) x 7.4 mm (V) 10.5 mm (diagonal)
Aspect Ratio	1:1
Number of Outputs	1 or 2
Saturation Signal	40,000 electrons
Output Sensitivity	12 $\mu\text{V}$ /electron
Quantum Efficiency KAI-1020-ABA (500nm)	44%
Quantum Efficiency KAI-1020-CBAR (620nm), G(540nm), B(460nm)	31%, 36%, 41%
Dark Noise	50 electrons rms
Dark Current (Typical)	<0.5 nA/cm <sup>2</sup>
Dynamic Range	58 dB
Blooming Suppression	100 X
Image Lag	<10 electrons
Smear	<0.03%
Maximum Data Rate	40 MHz/Channel (2 channels)
Frame Rate	
Progressive Scan, One Output	30 fps
Progressive Scan, Dual Outputs	48 fps
Interlaced Scan, One Output	49 fps
Integrated Vertical Clock Drivers	
Integrated Correlated Double Sampling (CDS)	
Integrated Electronic Shutter Driver	
Package	68 pin PGA or 64 pin CLCC
Cover Glass	AR coated, 2 sides

All parameters above are specified at T = 40°C

## DEVICE DESCRIPTION

### ARCHITECTURE

There are 4 light shielded rows followed 1004 photoactive rows. The first 2 and the last 2 photoactive rows are buffer rows giving a total of 1000 lines of image data.

In the single output mode all pixels are clocked out of the Video 1 output in the lower left corner of the sensor. The first 8 empty pixels of each line do not receive charge from the vertical shift register. The next 12 pixels receive charge from the left light-shielded edge followed by 1004 photo-sensitive pixels and finally 12 more light shielded pixels from the right edge of the sensor. The first and

last 2 photosensitive pixels are buffer pixels giving a total of 1000 pixels of image data.

In the dual output mode the clocking of the right half of the horizontal CCD is reversed. The left half of the image is clocked out Video 1 and the right half of the image is clocked out Video 2. Each row consists of 8 empty pixels followed by 12 light shielded pixels followed by 502 photosensitive pixels. When reconstructing the image, data from Video 2 will have to be reversed in a line buffer and appended to the Video 1 data.

## PHYSICAL DESCRIPTION

### Pin Description and Device Orientation

#### Pin Grid Array

When viewed from the top with the pin 1 index to the upper left, the center of the photoactive pixel array is offset 0.006" above the physical center of the package. The pin 1 index is located in the corner of the package above pins L2 and K1. When operated in single output mode the first pixel out of the sensor will be in the corner closest to VOUT1B (pin L9). The HCCD is parallel to the row of pins A10 to L10. In the pictures below, the VCCD transfers charge down.

Pin Grid Array Pin Description

## IMAGING PERFORMANCE

### OPTICAL SPECIFICATION

Symbol	Description	Min.	Nom.	Max.	Units	Notes	Sampling Plan
$QE_{max}$	Peak Quantum Efficiency	42	45		%	1	Design
$\lambda_{QE}$	Peak Quantum Efficiency Wavelength		490		nm	1	Design
$\theta_{QEh}$	Microlens Acceptance Angle (horizontal)	$\pm 12$	$\pm 13$		degrees	2	Design
$\theta_{QEv}$	Microlens Acceptance Angle (vertical)	$\pm 25$	$\pm 30$		degrees	2	Design
QE(540)	Quantum Efficiency at 540nm	38	40		%	1	Design
PNU	Photoresponse nonuniformity		5		%		Design
NL	Maximum Photoresponse Nonlinearity		2		%	3, 4, 18	Die
$\Delta G$	Maximum Gain Difference Between Outputs		10		%	3, 4, 18	Die
$\Delta NL$	Maximum Signal Error caused by Nonlinearity Differences		1		%	3, 4, 18	Die
	Dark Center Uniformity			12	$e^-$ rms	19, 20	Die
	Dark Global Uniformity			2	mVpp	19, 20	Die
	Global Uniformity			5	%rms	19, 20	Die
	Global Peak to Peak Uniformity			15	%pp	19, 20	Die
	Center Uniformity			0.7	%rms	19, 20	Die

### CCD SPECIFICATIONS

Symbol	Description	Min.	Nom.	Max.	Units	Notes	Sampling Plan
Vne	Vertical CCD Charge Capacity	54	60		$ke^-$		Design
Hne	Horizontal CCD Charge Capacity	110	120		$ke^-$		Design
Pne	Photodiode Charge Capacity	38	42		$ke^-$	5	Die
I <sub>d</sub>	Dark Current		0.2	0.5	nA/cm <sup>2</sup>	6	Die
Lag	Image Lag		< 10	50	$e^-$	7	Design
Xab	Antiblooming factor	100	300			1, 8, 9, 10, 11	Design
Smr	Vertical Smear		-75	-72	dB	1, 8, 9	Design

### CDS OUTPUT SPECIFICATION

Symbol	Description	Nominal	Units	Notes	Sampling Plan
P <sub>d</sub>	Power Dissipation	213	mW	12	Design
F <sub>-3dB</sub>	Bandwidth	140	MHz	12	Design
C <sub>L</sub>	Max Off-chip Load	10	pF	13	Design
A <sub>v</sub>	Gain	0.70		12	Design
$\Delta V/\Delta N$	Sensitivity	13	$\mu V/e^-$	12	Design
R	Output Impedance	160	$\Omega$	12	Design
V <sub>sat</sub>	Saturation Voltage	500	mV	5, 12	Die
I <sub>out</sub>	Output Bias Current	3.0	mA		Design

### GENERAL – MONOCHROME

Symbol	Description	Nominal	Units	Notes	Sampling Plan
n <sub>e-T</sub>	Total Camera Noise	42	$e^-$ rms	6, 14	Design
DR	Dynamic Range	60	dB	15	Design

### GENERAL COLOR

Symbol	Description	Nominal	Units	Notes	Sampling Plan
n <sub>e-T</sub>	Total Camera Noise	50	$e^-$ rms	6, 14	Design
DR	Dynamic Range	58	dB	15	Design

## POWER

Description	Nominal	Units	Notes
Single Channel CDS	213	mW	12
VCCD clock driver	71	mW	16
Electronic shutter driver	1.1	mW	
HCCD	122	mW	16, 17
Total Power	407	mW	12, 16

### Notes:

1. Measured with F/4 imaging optics.
2. Value is the angular range of incident light for which the quantum efficiency is at least 50% of  $QE_{max}$  at a wavelength of  $\lambda_{QE}$ . Angles are measured with respect to the sensor surface normal in a plane parallel to the horizontal axis ( $\theta_{QEh}$ ) or in a plane parallel to the vertical axis ( $\theta_{QEv}$ ).
3. Value is over the range of 10% to 90% of photodiode saturation.
4. Value is for the sensor operated without binning.
5. This value depends on the substrate voltage setting. Higher photodiode saturation charge capacities will lower the antiblooming specification. Substrate voltage will be specified with each part for 42 ke<sup>-</sup>.
6. Measured at 40°C, 40 MHz HCCD frequency.
7. This is the first field decay lag at 70% saturation. Measured by strobe illumination of the device at 70% of photodiode saturation, and then measuring the subsequent frame's average pixel output in the dark.
8. Measured with a spot size of 100 vertical pixels, no electronic shutter.
9. Measured with green light (500 nm to 580 nm).
10. A blooming condition is defined as when the spot size doubles in size.
11. Antiblooming factor is the light intensity which causes blooming divided by the light intensity which first saturates the photodiodes.
12. Single output power, 3mA load
13. With total output load capacitance of  $C_L = 10$  pF between the outputs and AC ground.
14. Includes system electronics noise, dark pattern noise and dark current shot noise at 40 MHz. Total noise measured on the KAI-1020 evaluation board.
15. Uses  $20\text{LOG}(P_{Ne}/n_{e^{-}})$
16. At 30 frames/sec, single output
17. This includes the power of the external HCCD clock driver.
18. For the sampling plan, measured at 10 MHz
19. Tested at 27 and 40°C
20. See Tests

### Sampling Plan

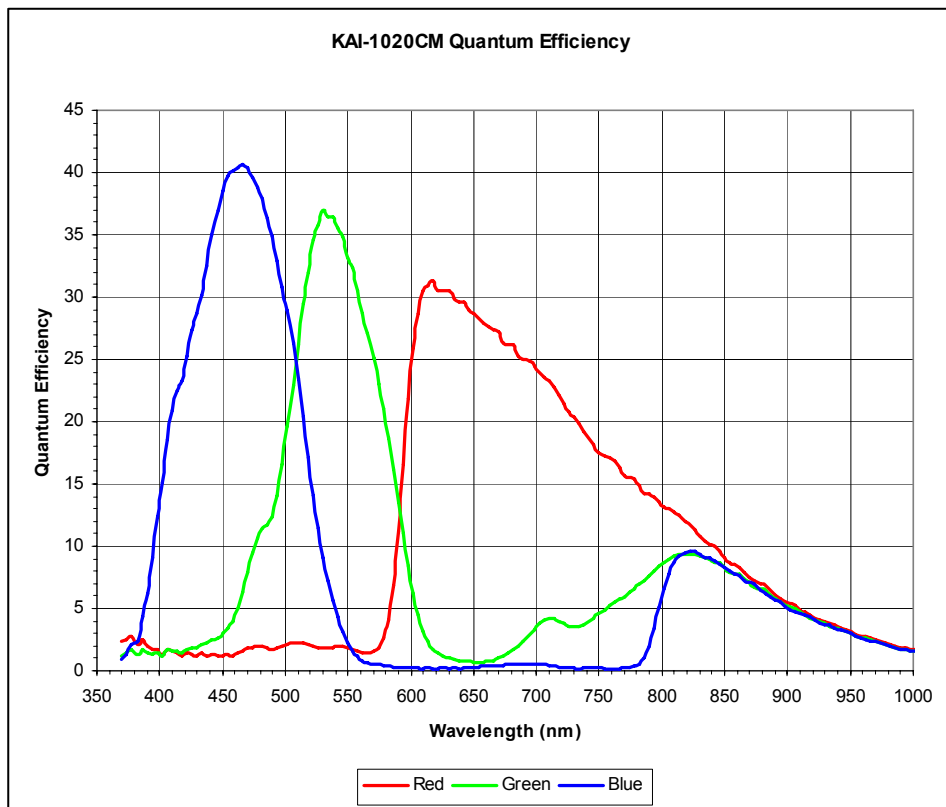

Sampling plan defined as "die" indicates that every device is verified against the specified performance limits. Sampling plan defined as "design" indicates a sampled test or characterization, at the discretion of Kodak, against the specified performance limits.

**TYPICAL PERFORMANCE CURVES**

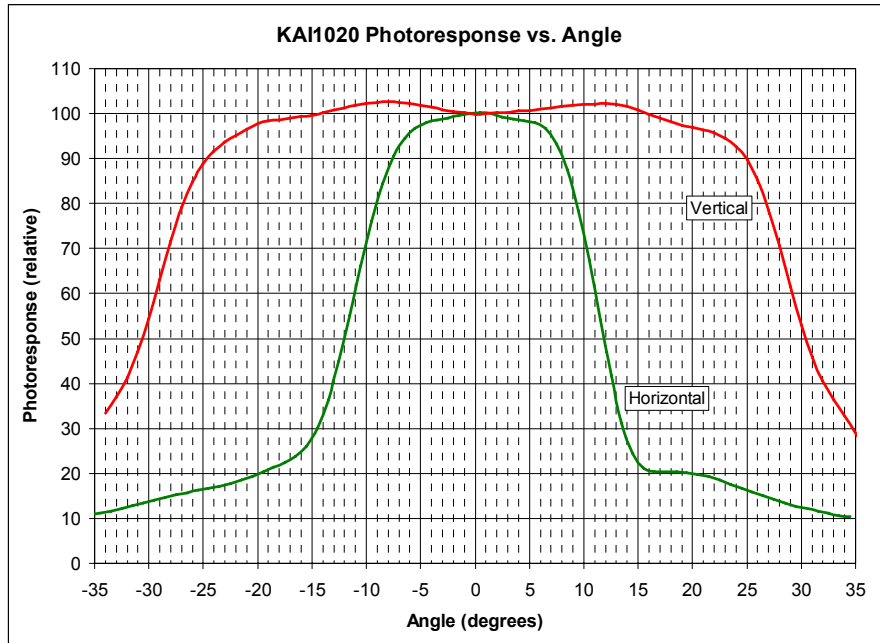

**MONOCHROME QUANTUM EFFICIENCY**

**COLOR QUANTUM EFFICIENCY**

PHOTORESPONSE VS. ANGLE

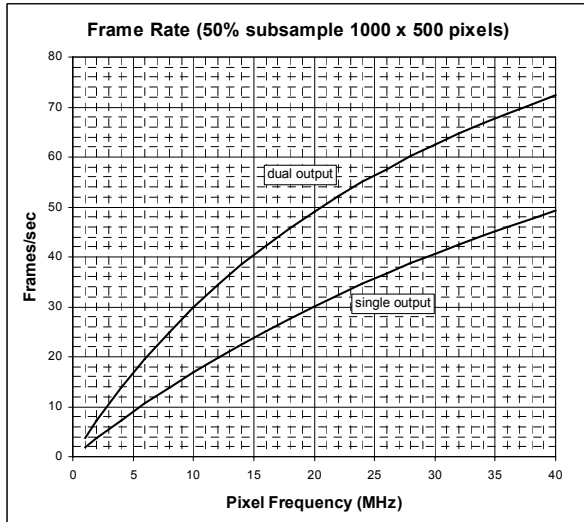

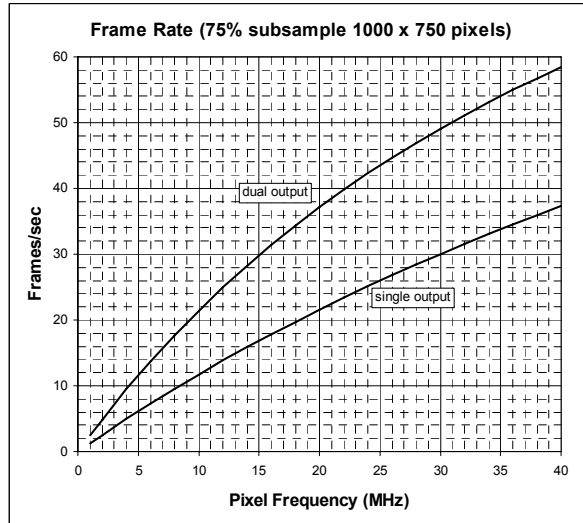

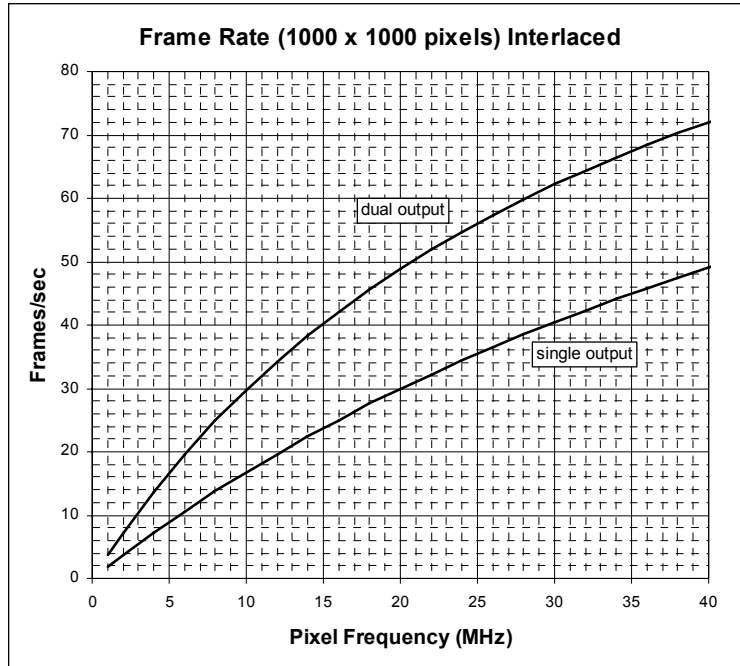

The horizontal curve is where the incident light angle is varied in a plane parallel to the HCCD.  
 The vertical curve is where the incident light angle is varied in a plane perpendicular to the HCCD.

SENSOR POWER

FRAME RATE

## DEFECT DEFINITIONS

### SPECIFICATIONS

Name	Definition	Maximum	Temperature(s) tested at (°C)	Notes	Test	Sampling Plan
Dark field major bright defective pixel	Defect $\geq$ 28mV	10	27, 40	1	6	Die
Bright field major dark or bright defective pixel	Defect $\geq$ 11%			7	Die	
Bright field minor dark defective pixel	Defect $\geq$ 5%	20 in Zone 2	27, 40	8	8	Die
Dark field minor bright defective pixel	Defect $\geq$ 14mV	100	27, 40	2	6	Die
Bright field dead dark pixel	Defect $\geq$ 40%	0	27, 40	5	7	Die
Bright field nearly dead dark pixel	Defect $\geq$ 20%	0 in Zone 1 1 in Zone 2	27, 40	5, 8	7	Die
Dark field saturated bright pixel	Defect $\geq$ 106mV	0	27, 40	3	6	Die
Dark field minor cluster defect	A group of 2 to 10 contiguous dark field minor defective pixels	0	27, 40	4		Die
Bright field minor cluster defect	A group of 2 to 10 contiguous bright field minor defective pixels	2 in Zone 2	27, 40	4, 8		Die
Major cluster defect	A group of 2 to 10 contiguous major defective pixels	0	27, 40	4		Die
Column defect	A group of more than 10 contiguous major defective pixels along a single column	0	27, 40			Die
Column Average Magnitude	Within +/-0.4% of regional average (5 columns)	0	27, 40	6, 7	9	Die

Notes:

- The defect threshold was determined by using a threshold of 8mV at an integration time of 33 milliseconds and scaling it by the actual integration time used of 117 msec.  
 $8\text{mV} \times (117 \text{ msec} / 33 \text{ msec}) = 28 \text{ mV}$
- The defect threshold was determined by using a threshold of 4mV at an integration time of 33 milliseconds and scaling it by the actual integration time used of 117 msec.  
 $4\text{mV} \times (117 \text{ msec} / 33 \text{ msec}) = 14 \text{ mV}$
- The defect threshold was determined by using a threshold of 30mV at an integration time of 33 milliseconds and scaling it by the actual integration time used of 117 msec.  
 $30\text{mV} \times (117 \text{ msec} / 33 \text{ msec}) = 106 \text{ mV}$
- The maximum width of any cluster defect is 2 pixels.
- Only dark defects.
- Local average is centered on column.
- See Test Regions of Interest for region used.
- See Figure 4 for zone 1 and 2 definitions.

### Defect Map

The defect map supplied with each sensor is based upon testing at an ambient (27°C) temperature. Minor point defects are not included in the defect map. All defective pixels are referenced to pixel 1,1 in the defect map (see Figure 2: Regions of Interest).

## TEST DEFINITIONS

### TEST CONDITIONS

Description	Condition	Notes
Frame time	117 msec	1
Horizontal clock frequency	10 MHz	
Light source (LED)	Continuous green illumination centered at 530 nm	2
Operation	Nominal operating voltages and timing	

Notes:

1. Electronic shutter is not used. Integration time equals frame time.
2. Green LED used : Nichia NSPG500S.

### Test System Conversion Factors

KAI-1020M output sensitivity: 13  $\mu$ V per electron

Test system gain (measured): 0.25 mV per ADU

Test system gain (calculated): 19 electrons per ADU

## TESTS

### 1. Dark field center uniformity

This test is performed under dark field conditions. Only the center 100 by 100 pixels of the sensor are used for this test (pixels 431,431 to pixel 530,530). See Figure 3: Center Region of Interest.

$$\text{Dark field center uniformity} = \text{Standard Deviation of center 100 by 100 pixels in electrons} * \left( \frac{\text{DPS Integration time}}{\text{Actual integration time used}} \right)$$

Units: e- rms

DPS integration time: Device Performance Specification Integration Time = 33 msec

### 2. Dark field global uniformity

This test is performed under dark field conditions. The sensor is partitioned into 100 sub regions of interest, each of which is 100 by 100 pixels in size. See Figure 1: Test Sub Regions of Interest. The average signal level of each of the 100 sub regions of interest is calculated. The signal level of each of the sub regions of interest is calculated using the following formula:

$$\text{Signal of ROI}[i] = (\text{ROI Average in ADU} - \text{Horizontal overclock average in ADU}) * \text{mV per count}$$

Where i = 1 to 100. During this calculation on the 100 sub regions of interest, the maximum and minimum signal levels are found.

The dark field global uniformity is then calculated as the maximum signal found minus the minimum signal level found.

Units: mVpp (millivolts peak to peak)

3. Global Uniformity

This test is performed with the light source illuminated to a level such that the output of the sensor is at 70% of saturation (approximately 364 mV). Prior to this test being performed the substrate voltage has been set such that the charge capacity of the sensor is 520mV. Global uniformity is defined as:

$$\text{Global Uniformity} = 100 * \left( \frac{\text{Active Area Standard Deviation}}{\text{Active Area Signal}} \right) \quad \text{Units: \%rms}$$

$$\text{Active Area Signal} = \text{Active Area Average} - \text{Horizontal Overclock Average}$$

4. Global Peak to Peak Uniformity

This test is performed with the light source illuminated to a level such that the output of the sensor is at 70% of saturation (approximately 364 mV). Prior to this test being performed the substrate voltage has been set such that the charge capacity of the sensor is 520mV. The sensor is partitioned into 100 sub regions of interest, each of which is 100 by 100 pixels in size. See Figure 1: Test Sub Regions of Interest. The average signal level of each of the 100 sub regions of interest (ROI) is calculated. The signal level of each of the sub regions of interest is calculated using the following formula

$$\text{Signal of ROI}[i] = (\text{ROI Average in ADU} - \text{Horizontal overclock average in ADU}) * \text{mV per count}$$

Where i = 1 to 100. During this calculation on the 100 sub regions of interest, the maximum and minimum signal levels are found.

The global peak to peak uniformity is then calculated as:

$$\text{Global Uniformity} = \frac{\text{Maximum Signal} - \text{Minimum Signal}}{\text{Active Area Signal}} \quad \text{Units: \%pp}$$

5. Center Uniformity

This test is performed with the light source illuminated to a level such that the output of the sensor is at 70% of saturation (approximately 364 mV). Prior to this test being performed the substrate voltage has been set such that the charge capacity of the sensor is 520mV. Defects are excluded for the calculation of this test. This test is performed on the center 100 by 100 pixels (See Test Regions of Interest and Figure 3: Center Region of Interest) of the sensor. Center uniformity is defined as:

$$\text{Center ROI Uniformity} = 100 * \left( \frac{\text{Center ROI Standard Deviation}}{\text{Center ROI Signal}} \right) \quad \text{Units: \%rms}$$

$$\text{Center ROI Signal} = \text{Center ROI Average} - \text{Horizontal Overclock Average}$$

6. Dark field defect test

This test is performed under dark field conditions. The sensor is partitioned into 100 sub regions of interest, each of which is 100 by 100 pixels in size. See Figure 1: Test Sub Regions of Interest. In each region of interest, the median value of all pixels is found. For each region of interest, a pixel is marked defective if it is greater than or equal to the median value of that region of interest plus the defect threshold specified.

7. **Bright field defect test**

This test is performed with the light source illuminated to a level such that the output of the sensor is at 70% of saturation (approximately 364 mV). Prior to this test being performed the substrate voltage has been set such that the charge capacity of the sensor is 520mV. The average signal level of all active pixels is found. The bright and dark thresholds are set as:

- Dark defect threshold = Active Area Signal \* threshold
- Bright defect threshold = Active Area Signal \* threshold

The sensor is then partitioned into 100 sub regions of interest, each of which is 100 by 100 pixels in size. See Figure 1: Test Sub Regions of Interest. In each region of interest, the average value of all pixels is found. For each region of interest, a pixel is marked defective if it is greater than or equal to the median value of that region of interest plus the bright threshold specified or if it is less than or equal to the median value of that region of interest minus the dark threshold specified.

Example for major bright field defective pixels:

- Average value of all active pixels is found to be 365 mV.
- Dark defect threshold: 365mV \* 11% = 40mV
- Bright defect threshold: 365mV \* 11% = 40mV
- Region of interest #1 selected. This region of interest is pixels 1,1 to pixels 100,100.
  - Median of this region of interest is found to be 366 mV.
  - Any pixel in this region of interest that is >= (366+40mV) 406mV in intensity will be marked defective.
  - Any pixel in this region of interest that is <= (366-40mV) 324mV in intensity will be marked defective.
- All remaining 99 sub regions of interest are analyzed for defective pixels in the same manner.

8. **Bright field minor defect test**

This test is performed with the light source illuminated to a level such that the output of the sensor is at 70% of saturation (approximately 364 mV). Prior to this test being performed the substrate voltage has been set such that the charge capacity of the sensor is 520mV. The average signal level of all active pixels is found. The dark thresholds is set as:

- Dark defect threshold = Active Area Signal \* threshold

The sensor is then partitioned into 2500 sub regions of interest, each of which is 20 by 20 pixels in size. In each region of interest, the average value of all pixels is found. For each region of interest, a pixel is marked defective if it is less than or equal to the median value of that region of interest minus the dark threshold specified.

Example for bright field minor defective pixels:

- Average value of all active pixels is found to be 365 mV.
- Dark defect threshold: 365mV \* 5% = 18mV
- Region of interest #1 selected. This region of interest is pixels 1,1 to pixels 20,20.
  - Median of this region of interest is found to be 366 mV.
  - Any pixel in this region of interest that is <= (366-18mV) 348mV in intensity will be marked defective.
- All remaining 2499 sub regions of interest are analyzed for defective pixels in the same manner.

9. **Bright field column average magnitude test**

This test is performed with the light source illuminated to a level such that the output of the sensor is at 70% of saturation (approximately 364 mV). Prior to this test being performed the substrate voltage has been set such that the charge capacity of the sensor is 520mV. A column is marked as defective if

$$100 * \text{abs} \left( \frac{\text{Avg}(\text{Column } n) - \text{Avg}(\text{Avg}(\text{Column } x))}{\text{Avg}(\text{Avg}(\text{Column } x))} \right) > 0.4 \quad \text{where } x=n-2 \text{ to } n+2$$

## TEST REGIONS OF INTEREST

Test Regions of Interest

Total number of pixels: 1028 (H) x 1008 (V)

Number of photo sensitive pixels: 1004 (H) x 1004 (V)

Number of active pixels: 1000 (H) x 1000 (V)

Active Area ROI: Pixel 1,1 to Pixel 1000,1000

Center ROI: Pixel 450,450 to Pixel 549,549

Column Magnitude Test ROI: Pixel 11,11 to Pixel 990, 990

Only the active pixels are used for performance and defect tests. See Figure 2: Regions of Interest

**Signal Level Calculation**

Signal levels are calculated by using the average of the region of interest under test and subtracting off the horizontal overlock region. The test system timing is configured such that the sensor is overlocked in both the vertical and horizontal directions. See Figure 2 for a pictorial representation of the regions.

Example: To determine the active area average in millivolts, the following calculation used:

$$\text{Active area signal (mV)} = (\text{Active area average} - \text{horizontal overlock average}) * \text{mV per count}$$

**OPERATION**

**SINGLE OR DUAL OUTPUT**

The KAI-1020 is designed to read the image out of one output at 30 frames/second or two outputs at 48 frames/second. In the dual output mode the right half of the horizontal shift register reverses its direction of charge transfer. The left half of the image is read out of video 1 and the right half of the image is read out of video 2.

There are no dark reference rows at the top and 4 dark rows at the bottom of the image sensor. The 4 dark rows should not be used for a dark reference level. The dark rows will contain smear signal from bright light sources. Use the 12 dark columns on the left or right side of the image sensor as a dark reference.

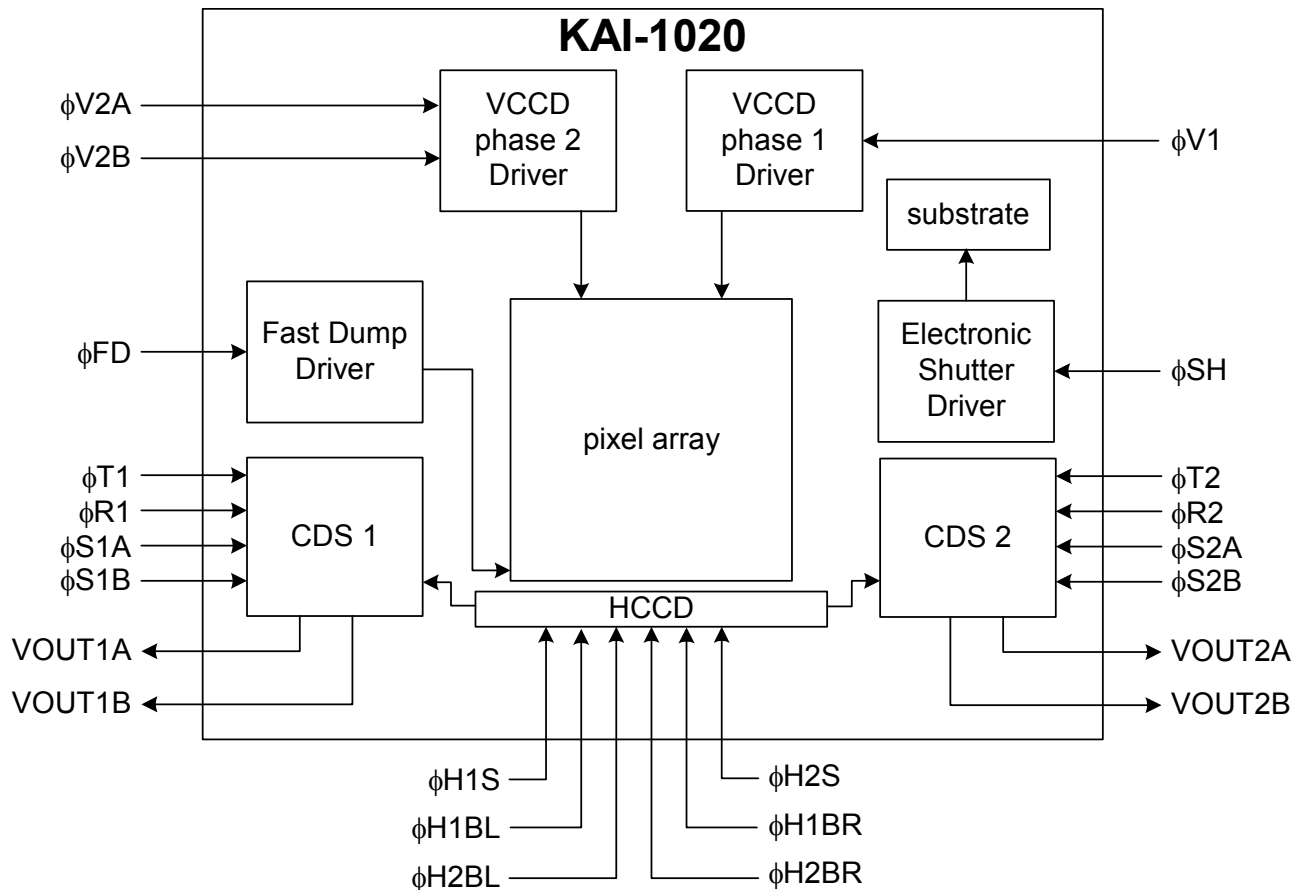

## THE KAI-1020 PIXEL

The pixel is  $7.4\ \mu\text{m}$  square. It consists of a light sensitive photodiode and an optically shielded vertical shift register. The vertical shift register is a charge-coupled device (VCCD). Each pixel is covered by a microlens to increase the light gathering efficiency of the photodiode.

Under normal operation, the image capture process begins with a  $4\ \mu\text{s}$  long pulse on the electronic shutter trigger input  $\phi\text{SH}$ . The electronic shutter empties all charge from every photodiode in the pixel array.

The photodiodes start collecting light on the falling edge of the  $\phi\text{SH}$  pulse. For each photon that is incident upon the  $7.4\ \mu\text{m}$  square area of the pixel, the probability of an electron being generated in the photodiode is given by the quantum efficiency (QE). At the end of the desired integration time, a  $10\ \mu\text{s}$  pulse on  $\phi\text{V2B}$  transfers the charge (electrons) collected in the photodiode into the VCCD. The integration time ends on the falling edge of  $\phi\text{V2B}$ .

HIGH LEVEL BLACK DIAGRAM

All timing inputs are driven by 5V logic. The image sensor has integrated clock drivers to generate the proper voltages for the internal CCD gates. There are two VCCD clock drivers. Both the phase 1 and phase 2 VCCD drivers control the shifting of charge through the VCCD. The phase 2 driver also controls the transfer of charge from the photodiodes to the VCCD.

There is an integrated fast dump driver, which allows an entire row of pixels to be quickly discarded without clocking the row through the HCCD.

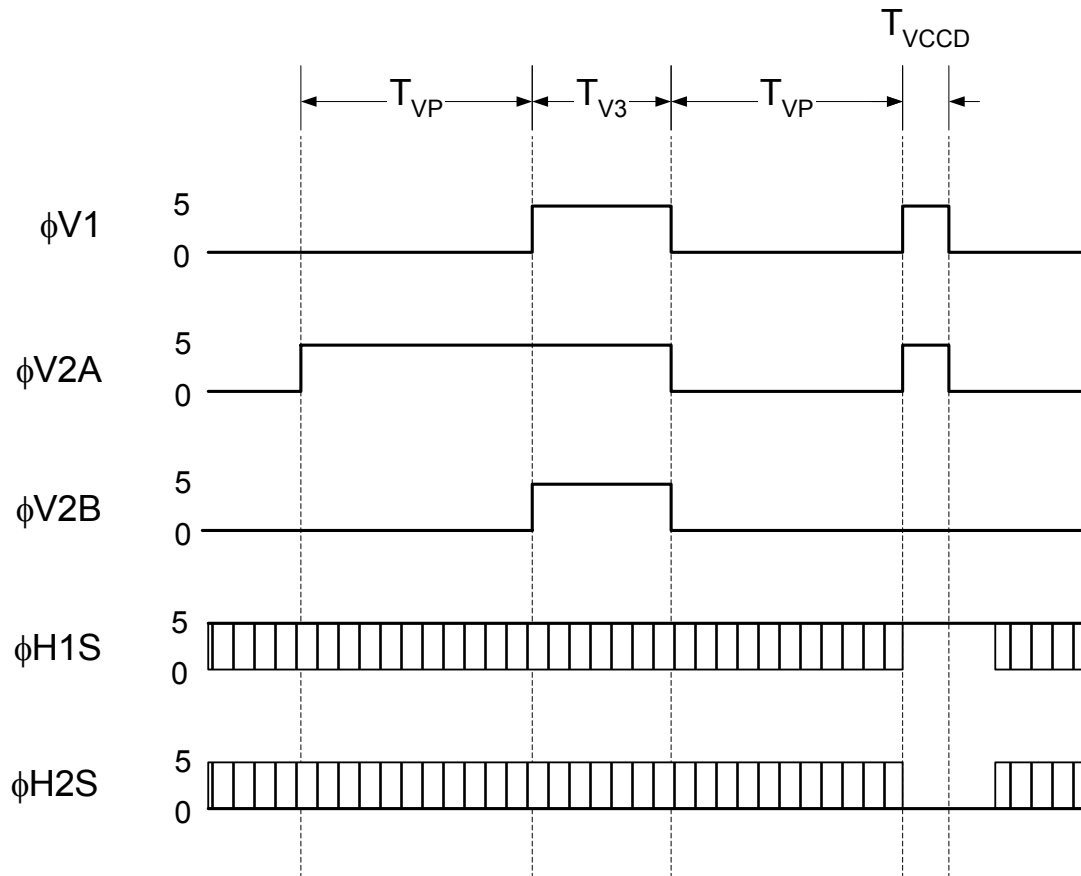

An integrated electronic shutter driver generates a >30 volt pulse on the substrate to simultaneously empty every photodiode on the image sensor.

Each of the two outputs has a correlated double sampling circuit to simplify the analog signal processing in the camera. The horizontal clock timing selects which outputs are active.

MAIN TIMING

VERTICAL FRAME TIMING

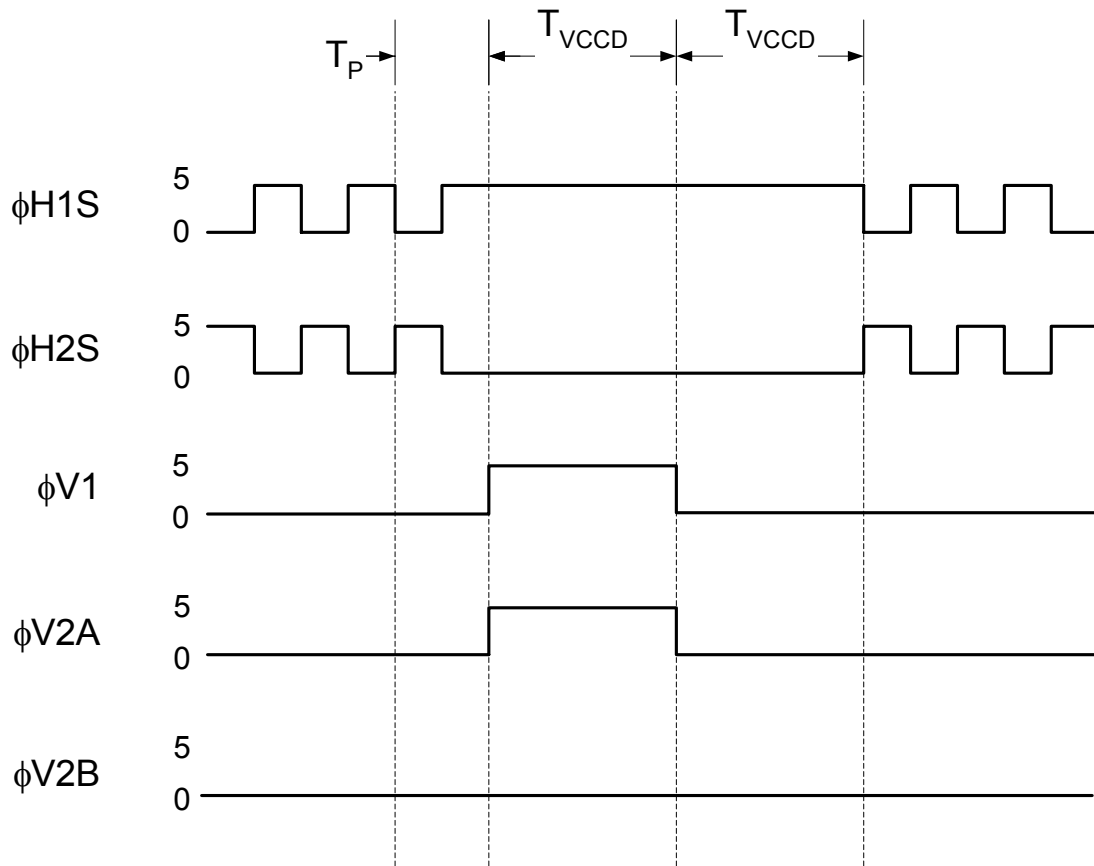

The vertical frame timing may begin once the last pixel of the image sensor has been read out of the HCCD. The beginning of the vertical frame timing is at the rising edge of  $\phi V2A$ . After the rising edge of  $\phi V2A$  there must be a delay of  $T_{VP}$   $\mu s$  before a pulse of  $T_{V3}$   $\mu s$  on  $\phi V2B$  and  $\phi V1$ . The charge is transferred from the photodiodes to the VCCD during the time  $T_{V3}$ . The falling edge of  $\phi V2B$  marks the end of the photodiode integration time. After the pulse on  $\phi V2B$  the  $\phi V1$  and  $\phi V2A$  should remain idle for  $T_{VP}$   $\mu s$  before the horizontal line timing period begins. This allows the clock and well voltages time to settle for efficient charge transfer in the VCCD.

All HCCD and CDS timing inputs should run continuously through the vertical frame timing period. For an extremely short integration time, it is allowed to place an electronic shutter pulse on  $\phi SH$  at any time during the vertical frame timing. The  $\phi SH$  and  $\phi V2B$  pulses may be overlapped. The integration time will be from the falling edge of  $\phi SH$  to the falling edge of  $\phi V2B$ .

## HORIZONTAL LINE TIMING

When the  $\phi V2A$  and  $\phi V1$  timing inputs are pulsed, charge in every pixel of the VCCD is shifted one row towards the HCCD. The last row next to the HCCD is shifted into the HCCD. When the VCCD is shifted, the timing signals to the HCCD must be stopped.  $\phi H1S$  must be stopped in the high state and  $\phi H2S$  must be stopped in the low state. The HCCD clocking may begin  $T_{VCCD}$   $\mu s$  after the falling edge of the  $\phi V2A$  and  $\phi V1$  pulse. The timing inputs to the CDS should run continuously through the horizontal line timing.

The HCCD has a total of 1036 pixels. The 1028 vertical shift registers (columns) are shifted into the center 1028 pixels of the HCCD. There are 8 pixels at both ends of the HCCD which receive no charge from a vertical shift register. The first 8 clock cycles of the HCCD will be empty pixels (containing no electrons). The next 12 clock cycles will contain only electrons generated by dark current in the VCCD and photodiodes. The next 1004 clock cycles will contain photo-electrons (image data). Finally, the last 12 clock cycles will contain only electrons generated by dark current in the VCCD and photodiodes. Of the 12 dark columns, the first and last

dark columns should not be used for determining the zero signal level. Some light does leak into the first and last dark columns. Only use the center 10 columns of the 12 column dark reference.

When the HCCD is shifting valid image data, the timing inputs to the electronic shutter driver ( $\phi SH$ ), VCCD driver ( $\phi V2A$ ,  $\phi V2B$ ,  $\phi V1$ ), and fast dump drivers ( $\phi FD$ ) should be held at the low level. This prevents unwanted noise from being introduced into the CDS circuit.

The HCCD is a type of charge coupled device known as a pseudo-two phase CCD. This type of CCD has the ability to shift charge in two directions. This allows the entire image to be shifted out to the video 1 output CDS, or to the video 2 output CDS (left/right image reversal). The HCCD is split into two equal halves of 522 pixels each. When operating the sensor in single output mode the two halves of the HCCD are shifted in the same direction. When operating the sensor in dual output mode the two halves of the HCCD are shifted in opposite directions. The direction of charge transfer in each half is controlled by the  $\phi H1BL$ ,  $\phi H2BL$ ,  $\phi H1BR$ , and  $\phi H2BR$  timing inputs.

### Single Output

To direct all pixels to the video 1 output make the following HCCD connections:

$$\phi H1S = \phi H1BL, \phi H2BR$$

$$\phi H2S = \phi H2BL, \phi H1BR$$

To direct all pixels to the video 2 output make the following HCCD connections:

$$\phi H1S = \phi H2BL, \phi H1BR$$

$$\phi H2S = \phi H1BL, \phi H2BR$$

In each case the first 8 pixels will contain no electrons, followed by 12 dark reference pixels containing only electrons generated by dark current, followed by 1004 photo-active pixels, followed by 12 dark reference pixels. The HCCD must be clocked for at least 1028 cycles. The VCCD may be clocked immediately after the 1028th HCCD clock cycle.

If the sensor is to be permanently operated in single output mode through video 1, then VDD2 (pins B8, and B10) may be connected to GND. This disables the video 2 CDS and lowers the power consumption.

If the sensor is to be permanently operated in single output mode through video 2, then VDD1 and VDD2 supplies must be +15 V. The VDD1 supplies must always be at +15 V for the sensor to operate properly.

### Dual Output

To use both outputs for faster image readout, make the following HCCD connections:

$$\phi H1S = \phi H1BL, \phi H1BR$$

$$\phi H2S = \phi H2BL, \phi H2BR$$

For both outputs the first 8 HCCD clock cycles contain no electrons, followed by 12 dark reference pixels containing only dark current electrons, followed by 502 photo-active pixels. This adds up to 522 pixels, but the HCCD should be clocked for at least 523 cycles before the next VCCD line shift takes place. The extra HCCD clock cycle ensures that the signal from the last pixel exits the CDS circuit before the VCCD drivers switch the gate voltages. This extra cycle is not needed for the single output modes because in that case, the last pixel is from a column of the dark reference which is not used. See the section on correlated double sampling for a description of the one pixel delay in the CDS circuit.

## ELECTRONIC SHUTTER

### Substrate Voltage

The voltage on the substrate, pins L1 and L5, determines the charge capacity of the photodiodes. When  $V_{SUB}$  is 8 volts the photodiodes will be at their maximum charge capacity. Increasing  $V_{SUB}$  above 8 volts decreases the charge capacity of the photodiodes until 30 volts when the photodiodes have a charge capacity of zero electrons. Therefore, a short pulse on  $V_{SUB}$ , with a peak amplitude greater than 30 volts, empties all photodiodes and provides the electronic shuttering action.

### Substrate Voltage and Antiblooming

It may appear the optimal substrate voltage setting is 8 volts to obtain the maximum charge capacity and dynamic range. While setting  $V_{SUB}$  to 8 volts will provide the maximum dynamic range, it will also provide the minimum antiblooming protection.

The KAI-1020 VCCD has a charge capacity of 60,000 electrons (60 ke). If the  $V_{SUB}$  voltage is set such that the photodiode holds more than 60 ke, then when the charge is transferred from a full photodiode to VCCD, the VCCD will overflow. This overflow condition manifests itself in the image by making bright spots appear elongated in the vertical direction. The size increase of a bright spot is called blooming when the spot doubles in size.

The blooming can be eliminated by increasing the voltage on  $V_{SUB}$  to lower the charge capacity of the photodiode. This ensures the VCCD charge capacity is greater than the photodiode capacity. There are cases where an extremely bright spot will still cause blooming in the VCCD. Normally, when the photodiode is full, any additional electrons generated by photons will spill out of the photodiode. The excess electrons are drained harmlessly out to the substrate. There is a maximum rate at which the electrons can be drained to the substrate.

If that maximum rate is exceeded, (say, for example, by a very bright light source) then it is possible for the total amount of charge in the photodiode to exceed the VCCD capacity. This results in blooming.

The amount of antiblooming protection also decreases when the integration time is decreased.

There is a compromise between photodiode dynamic range (controlled by  $V_{SUB}$ ) and the amount of antiblooming protection. A low  $V_{SUB}$  voltage provides the maximum dynamic range and minimum (or no) antiblooming protection. A high  $V_{SUB}$  voltage provides lower dynamic range and maximum antiblooming protection. The optimal setting of  $V_{SUB}$  is written on the container in which each KAI-1020 is shipped. The given  $V_{SUB}$  voltage for each sensor is selected to provide antiblooming protection for bright spots at least 100 times saturation, while maintaining at least 500 mV of dynamic range.

A detailed discussion of antiblooming and smear may be found in IEEE Transactions on Electron Devices vol. 39 no. 11, pg. 2508.

### Electronic Shutter Timing

The electronic shutter provides a method of precisely controlling the image exposure time without any mechanical components. If an integration time of  $T_{INT}$  is desired, then the substrate voltage of the sensor is pulsed to at least 30 volts  $T_{INT}$  seconds before the photodiode to VCCD transfer pulse on  $\phi V2B$ . The large substrate voltage pulse is generated by the KAI-1020. The electronic shutter is triggered by a 5 volt pulse on  $\phi SH$ . Use of the electronic shutter does not have to wait until the previously acquired image has been completely read out of the VCCD. The electronic shutter pulse may be added to the end of the horizontal line timing and just after the last pixel has been read out of the HCCD.  $\phi H1S$  and  $\phi H2S$  must be clocked during the electronic shutter pulse.

### FAST DUMP

The KAI-1020 has the ability to rapidly discard (fast dump, FD) entire lines of the image. The fast dump is a drain attached to the last row of the VCCD just before the HCCD. When the fast dump is activated by taking  $\phi FD$  high, charge from the VCCD goes into the drain instead of into the HCCD.

This timing diagram shows how two lines are dumped and the third is read out.  $\phi FD$  should go high once the last pixel of the preceding line has been read out. Cycle the VCCD for the number of rows to be dumped. The above timing diagrams shows two rows being dumped. When the proper number of rows have been dumped bring  $\phi FD$  low. Then clock the VCCD through one more cycle to shift a row into the HCCD.

The fast dump can be used to sub-sample the image for increased frame rates. For example, by dumping the even numbered lines, the image will be sub-sampled by a factor of 2 and the frame rate will almost increase by a factor of 2. Horizontal sub-sampling is not possible. The HCCD must always be cycled for the entire number of pixels in one line.

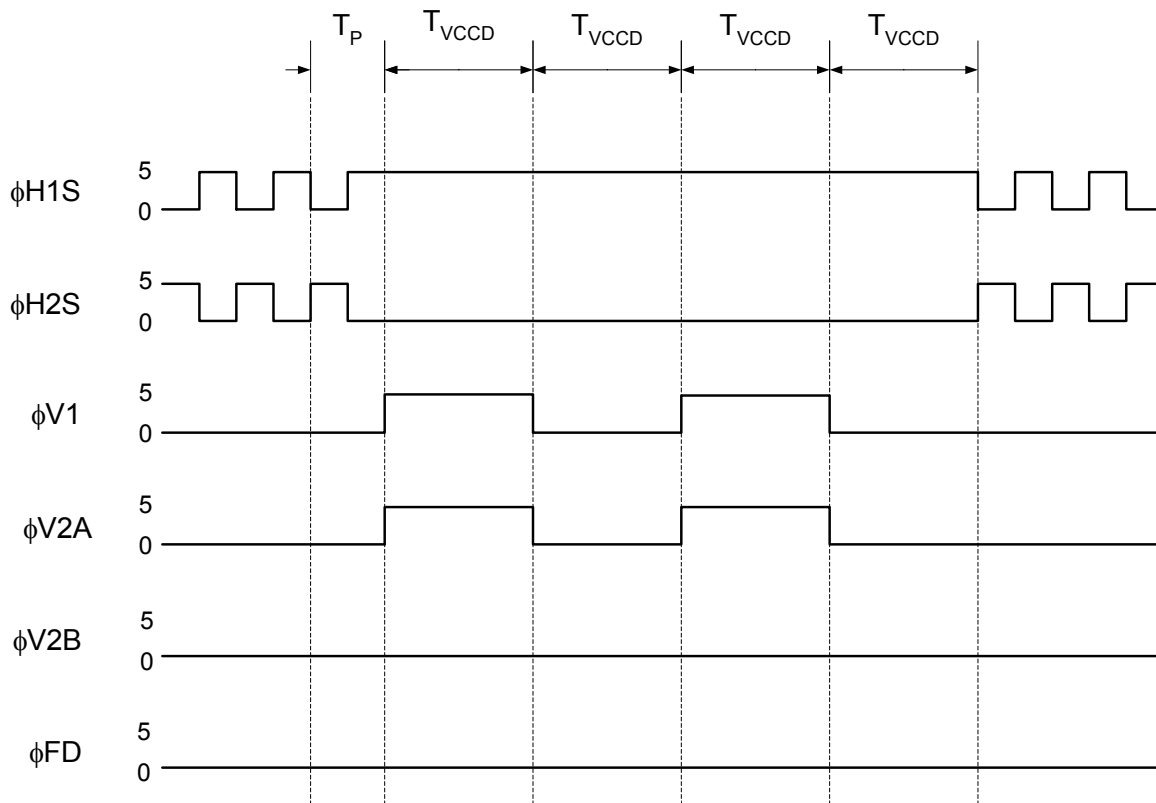

Another way to increase the frame rate is through sub-windowing. For example, suppose only the center 512 lines of the image are needed. Turn on the fast dump and clock the VCCD for 256 lines. Then turn off the fast dump and clock the VCCD (and HCCD) for 512 lines. Finally, turn the fast dump on again and clock the VCCD for 240 lines.

## BINNING AND INTERLACED MODES

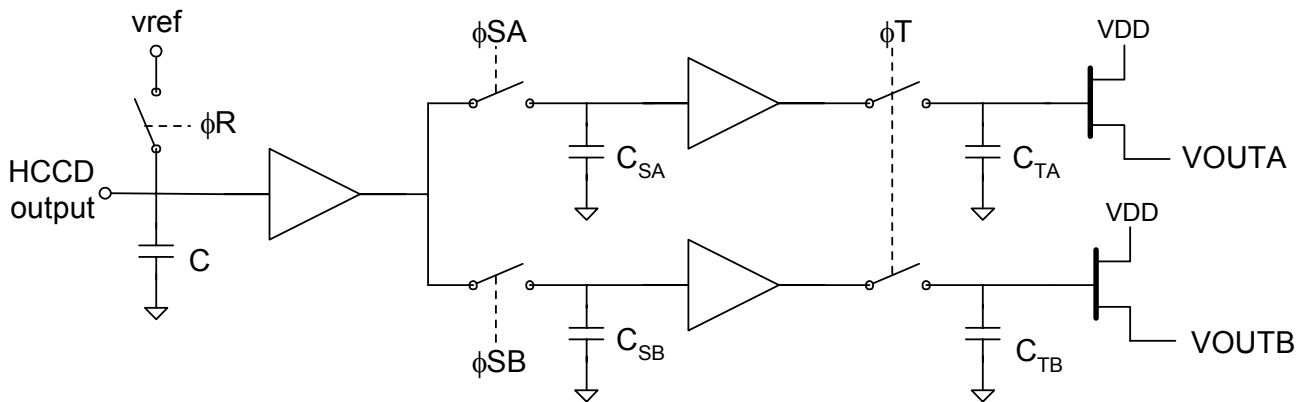

Binning is a readout mode of progressive scan CCD image sensors where more than one row at a time is clocked into the HCCD before reading out the HCCD. This timing mode sums two or more rows together. It increases the frame rate because there are fewer total rows to read out of the HCCD. The following timing diagram shows how two rows are summed together:

When binning two rows together only 504 rows need to be read out of the HCCD instead of the normal 1008 rows. The HCCD will hold up to two VCCD rows of full signal without blooming. Binning more than two rows may cause horizontal blooming for saturated signal levels.

Interlaced readout is a form of binning. To read out the even field use binning to sum together rows 0+1, rows 2+3, ... rows 1006+1007. To read out the odd field use binning to read out rows 0+1+2, rows 3+4, rows 5+6, ... rows 1005+1006, rows 1007+1008. The odd field may also be read out as row 0, rows 1+2, rows 3+4, ... rows 1005+1006. See the Interlaced – Field Integration section for an example of interlaced timing.

## CORRELATED DOUBLE SAMPLING (CDS)

Correlated double sampling is a method of measuring the amount of charge in each pixel. The electrons in the last pixel of the HCCD are transferred onto a very small sensing capacitor,  $C$ , on the falling edge of  $\phi_{H2S}$ . The voltage on  $C$  will change by about  $20 \mu\text{V}$  for each electron that was in the HCCD. The process of measuring the amount of charge begins by resetting the value of  $C$  to an internally generated reference voltage,  $v_{\text{ref}}$ . A short pulse on  $\phi_R$  at the rising edge of  $\phi_{H2S}$  will reset  $C$ . After  $C$  has been reset, its voltage is sampled and stored on  $C_{SA}$  by a short pulse on switch  $\phi_{SA}$ . Then on the falling edge of  $\phi_{H2S}$ , electrons are transferred onto the capacitor,  $C$ . The new voltage on  $C$  is sampled and stored on  $C_{SB}$  by a short pulse on switch  $\phi_{SB}$ . These two sampled voltages are then transferred to capacitors  $C_{TA}$  and  $C_{TB}$  by a short pulse on  $\phi_T$ .  $\phi_T$  and  $\phi_R$  generally occur at the same time. An external operational amplifier is used to subtract the two voltages on  $VOUTA$  and  $VOUTB$ . The output of the op-amp will be proportional to the number of electrons contained in one pixel. Note that it takes one entire pixel clock cycle for the value of the pixel to appear on  $VOUTA$  and  $VOUTB$ . The A and B outputs of the CDS circuit will be in the range of 7 to 11 volts.

### CDS Timing Edge Alignment

1. The edge alignments of the CDS timing pulses  $\phi_{SA}$ ,  $\phi_{SB}$ ,  $\phi_T$ , and  $\phi_R$  are critical to proper operation of the CDS circuit.
2. The falling edge of  $\phi_R$  must not overlap the rising edge of  $\phi_{SA}$
3. The falling edge of  $\phi_{SA}$  must come at the same time or before the falling edge of  $\phi_{H2}$
4. The rising edge of  $\phi_{SB}$  must come after the falling edge of  $\phi_{H2}$
5. The falling edge of  $\phi_{SB}$  must come before the rising edge of  $\phi_R$
6. The rising edge of  $\phi_R$  may come before the rising edge of  $\phi_{H2}$
7.  $\phi_T$  should always be driven by the same timing signal as  $\phi_R$
8. The pulse widths should be set such that  $\phi_R$ ,  $\phi_{SA}$ , and  $\phi_{SB}$  are  $1/3$  of  $T_p$

### Disabling the CDS

There may be instances when the camera designer may want to use an external CDS. Such cases may occur at pixel clock frequencies 20MHz or slower where integrated CDS, analog to digital converter (A/D), and auto offset/gain circuits are available. These external CDS circuits require the raw unprocessed video waveform. The raw video can be obtained by permanently turning on the  $\phi_{SA}$ ,  $\phi_{SB}$ , and  $\phi_T$  switches by connecting them to a voltage in the range of 8 to 10V (the V2HIGH supply voltage, for example). Then place a load of 4mA to 5mA on VOUTA and a load of 0.1mA on VOUTB. VOUTA will be the raw video output suitable for external CDS circuits. The 5mA load may be a 2.0k $\Omega$  resistor and the 0.1mA load may be an 80k $\Omega$  resistor to GND. An external CDS is not recommended for pixel frequencies above 20MHz.

## TIMING AND VOLTAGE SPECIFICATIONS

### Absolute Maximum Ratings

		Min.	Max.	Units	Notes
Temperature	Operation without damage	-50	70	C	
	Storage	-55	70	C	
Voltage between pins	VSUB to GND	8	20	V	1
	VDD to GND	0	17	V	
	$\phi V1$ to $\phi V2$ , $\phi FD$ to $\phi V1$ , $\phi V2$	-10	10	V	
	$\phi H1$ to $\phi H2$	-8	8	V	
	$\phi R$ , $\phi T$ , $\phi SA$ , $\phi SB$ to GND	-9	12	V	
	$\phi H1$ , $\phi H2$ to $\phi V1$ , $\phi V2$	-9	10	V	
Current	Video Output Bias Current	0	7	mA	2

Notes:

- For electronic shuttering VSUB may be pulsed to 35 V for up to 10  $\mu$ s.
- Note that the current bias effects the amplifier bandwidth.

### Timing

Time	Min.	Nominal	Max.	Units
$T_P$	25	25	500	ns
$T_{VCCD}$	3.6	3.6	10	$\mu$ s
$T_{VP}$	20	25	40	$\mu$ s
$T_{V3}$	8	10	15	$\mu$ s

### Bias Voltages

Bias	Min (Volts)	Nominal (Volts)	Max (Volts)	Peak Current (mA)	Peak Current Frequency	Avg. Current (mA)
V1S5	4	5	6	2	2L	0.13
V1MID	-1.5	-1.2	-1.0	110	L	3
V1LOW	-9.5	-9	-8.5	110	L	3
V2S5	4	5	6	2	2L	0.5
V2S9	8	9	10	2	F	0.3
V2HIGH	8	9	10	110	L	0.01
V2MID	-1.5	-1.2	-1.0	110	L	3
V2LOW	-9.5	-9	-8.5	110 220	L F	3.8
VDD1	14.5	15	15.5			14
VDD2	14.5	15	15.5			14
VSH15	14	15	16	1	F	0.08
VSUB	8	*	14			0.03

Average currents are for 30 frames/second

Peak switching currents are for less than 1  $\mu$ s duration

L = once per line time, 2L = twice per line time, F = once per frame time

\* substrate bias voltage for a 500mV output range is written on the shipping container for each part

### Power Up Sequence

- Power up VSUB, V1LOW, V2LOW first
- Then power up VDD, VSH15, V2S5, V1S5, V1MID, V2MID and V2HIGH
- Then after the coupling capacitors on all of the timing inputs have charged, begin clocking the timing inputs.

Any positive voltage should never be allowed to go negative. Any negative voltage should never be allowed to go positive.

Note that the shutter driver clock input does not use a coupling capacitor. It must be driven directly from a 5V logic buffer as shown in the evaluation board schematic.

**Pulse Amplitudes**

<b>Clock</b>	<b>Min. Amplitude (volts)</b>	<b>Coupling</b>	<b>Min. Coupling Capacitor Value (<math>\mu</math>F)</b>	<b>Max. Coupling Capacitor Value (<math>\mu</math>F)</b>
$\phi$ SH	3.5	DC	--	--
$\phi$ H1	4.7	AC	0.1	0.47
$\phi$ H2	4.7	AC	0.1	0.47

## HORIZONTAL CCD DRIVE CIRCUIT

single output only

dual output only

selectable single or dual output

The HCCD clock inputs should be driven by buffers capable of driving a capacitance of 60pF and having a full voltage swing of at least 4.7 V. A 74AC04 or equivalent is recommended to drive the HCCD. The HCCD requires a 0 to -5V clock. A negative clock level is easily obtained by capacitive coupling and a diode to clamp the high level to GND. Every HCCD clock input has a 300kΩ on chip resistor to GND.

The inputs to the above circuits, H1 and H2, are 5V logic from the timing generator (a programmable gate array for example). If the camera is to have selectable single or dual output modes of operation, then the timing logic needs to generate two extra signals for the H1BR and H2BR timing. For single output mode program the timing such that H1BR=H2 and H2BR=H1. For dual output mode program the timing such that H1BR=H1 and H2BR=H2.

## VERTICAL CCD

The VCCD clock inputs,  $\phi V2A$ ,  $\phi V2B$ ,  $\phi V1$ , and  $\phi FD$  have a capacitive load of approximately 10pF. Each input is connected to V2LOW and V1LOW by a 60k $\Omega$  internal resistor. There is also an internal diode connected to V2LOW and V1LOW. The 5V logic drivers must be connected to the sensor inputs through capacitors. These inputs require a clock of at least 4 V amplitude. Most PGA's can drive these inputs directly. The external capacitor and internal diode level shift the 0V to 5V input to V2LOW to V2LOW + 5.

The on chip VCCD clock drivers switch their outputs, V1OUT and V2OUT, between the supply voltages V1LOW, V1MID, V2LOW, V2MID, and V2HIGH. The truth table correlating the voltage on V1OUT and V2OUT to the timing inputs is:

$\phi V1$	V1OUT
L	V1MID
H	V1LOW

$\phi V2A$	$\phi V2B$	V2OUT
L	L	V2LOW
H	L	V2MID
L	H	V2HIGH
H	H	V2HIGH

L = logic low level  
H = logic high level

The output of the VCCD driver is connected to the VCCD gates by wiring V1OUT to V1IN and V2OUT to V2IN. The fast dump driver has no external output. It is wired internally to the VCCD fast dump gate.

## ELECTRONIC SHUTTER

The electronic shutter input,  $\phi$ SH, is the only input driven directly by CMOS logic. No capacitive coupling is required.  $\phi$ SH (pin B3) has approximately a 10pF load. The logic low level must be less than 0.5 V and the logic high level must be greater than 3.5 V. Most programmable gate arrays can drive  $\phi$ SH directly. The on chip electronic shutter driver is a charge pumping circuit. It uses C1, C2, D1, and D2 to generate a >25V pulse that is added onto the substrate DC bias voltage. The substrate bias voltage is set by a trim-pot R2 or by some programmable voltage source. The substrate bias voltage absolutely **MUST** be adjustable. The camera designer **CAN NOT** rely on every KAI-1020 image sensor requiring the same substrate bias. An adjustment range of 8 to 13V must be allowed. Each image sensor has the optimal substrate bias voltage (as measured on the VSUB pin) printed on the shipping container.

The minimum allowed voltage on VSUB is 8 V. Lower voltages may destroy the CDS and clock driver circuits.

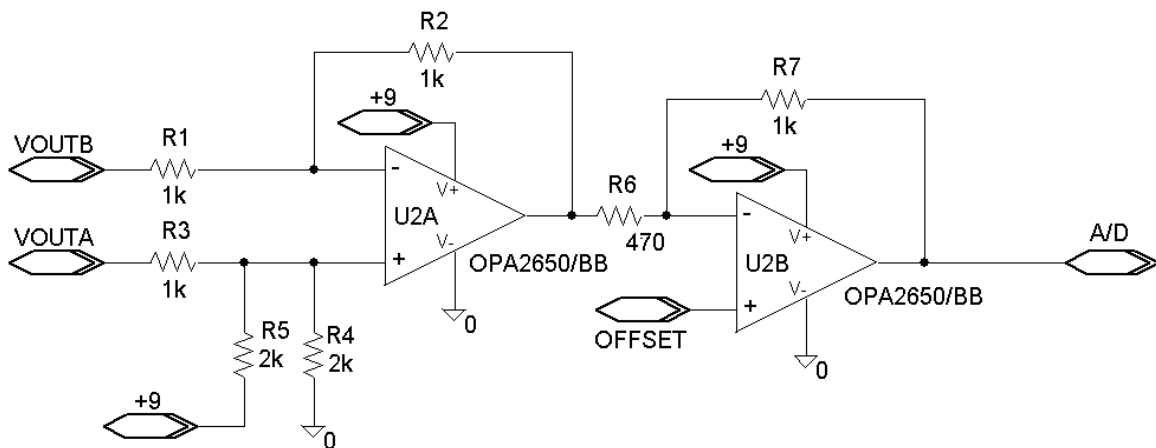

## CDS TIMING INPUTS

The CDS timing inputs  $\phi_R$ ,  $\phi_T$ ,  $\phi_{SA}$ , and  $\phi_{SB}$  should be driven by CMOS logic with fast rise and fall times and an amplitude of at least 4.7 V. The capacitance of each pin on the sensor is approximately 10pF. The pulses are level shifted positive by 1 V or 2 V on the sensor. If driving this input directly from a programmable gate array, be aware that some PGA's do not have outputs with amplitudes of 4.7V. It is recommended that the CDS timing inputs be driven by a 74AC04 to insure a 5V pulse amplitude with fast edges.

If the camera will only operate in single output mode then the  $\phi_{R2}$ ,  $\phi_{T2}$ ,  $\phi_{S2A}$ , and  $\phi_{S2B}$  inputs should be connected to GND. All CDS timing inputs must be coupled with a capacitor.

## CDS OUTPUT CIRCUIT

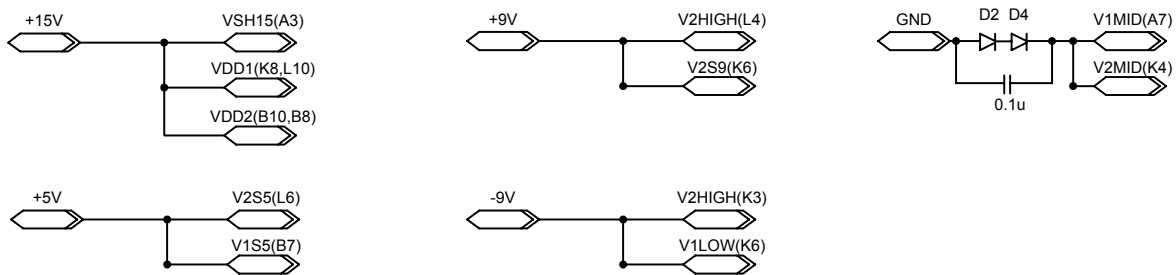

In the above schematic the differential video outputs VOUTB and VOUTA are subtracted by op-amp U2A. The video outputs will have a DC level of 7 to 11V. U2B then inverts the signal and applies a gain of 2.1 relative to the offset voltage. The output of U2B will match the 500mV output range of the KAI-1020 to the 1V input range of the analog to digital converter (A/D)

VOUTB will swing in the negative direction with increasing light level. The output of U2A will swing in the positive direction with increasing light level. The output of U2B (input to the A/D) will swing in the negative direction. This means the A/D output will be 0 counts when the image sensor is saturated. The digital data will have to be inverted before being transmitted to a digital image capture device. See the KAI-1020 evaluation board schematic for a simple method of inverting the data with no additional components.

The offset will have to be dynamically adjusted to match the zero light level of the image sensor. A circuit should examine the digital data in the dark reference columns and adjust the offset voltage of U2B to maintain a constant zero reference level in the A/D converter. The dynamic adjustment of the offset voltage will remove most temperature dependent drifts. Small temperature-dependant gain changes will still be present. See the KAI-1020 evaluation board schematic for an example of a circuit to generate the offset voltage.

This output circuit provides 10 bits of dynamic range on the KAI-1020 evaluation board. It is not the optimum circuit. For optimum differential common mode noise rejection and linearity, the CDS output circuit should take into account the 160  $\Omega$  impedance of the CDS output drive transistor.

## POWER SUPPLIES

The V1MID and V2MID connections must be set to  $-1.0$  to  $-1.5$ V. Since V1MID and V2MID only sink current, two diodes can be used to set this voltage.

If the sensor is to use only the single output mode, then VDD2(B10,B8) can be connected to GND. VOUT2A(A9) and VOUT2B(A10) also should be connected to GND in the single output only mode.

All other pins have no connection. All outputs are driven by low voltage differential line drivers (LVDS) except for the field index which is TTL.

## POWER CONNECTOR

The evaluation board requires +15 V, -15 V, and +5 V. The current draw for each supply is:

Supply	Current (mA)
+15	62
-15	18
+5	780

## MODE SWITCH

Switch	On	Off
1	Fast Dump off	Fast Dump on
2	1 output	2 outputs
3	---	----
4	Progressive scan	Interlaced

When the fast dump is activated the timing dumps the first 256 lines, then reads out 512 lines of image data, and finally it dumps the last 240 lines. The resulting image is 1000 columns by 512 rows. The interlaced mode timing is not programmed to support fast dumping.

## EXPOSURE SWITCH

All exposure times are in  $\mu$ s. Electronic shuttering is not programmed into the timing generator for interlaced mode.

Exposure Setting	FD off		FD on	
	1 output	2 outputs	1 output	2 outputs
0	33300	20600	20600	14160
1	16400	10160	6000	4400
2	7960	4960	3000	2540
3	3740	2320	1860	1840
4	1616	1016	1700	1700
5	564	362	824	824
6	298	198	460	460
7	68	55	93	93

## SUBSTRATE VOLTAGE TRIM

This variable resistor allows the substrate voltage to be varied from 0V to 15V. Adjusting this voltage will change the charge capacity and anti-blooming of the pixel photodiodes. Do not adjust the voltage below 8 V.

## EVALUATION BOARD NOTES

### Timing

The main timing is generated by a programmable gate array U8. The HCCD drive is setup for selectable single or dual output by inverting the H2BR and H2BL timing signals depending on the setting of the mode switch SW1.

The short pulses for  $\phi_R$ ,  $\phi_T$ ,  $\phi_{SA}$ , and  $\phi_{SB}$  are generated by combining (logical and/or) the outputs of the delay line U10. Each tap on U10 delays the system clock by 2.5ns.

The amount of noise in the KAI1020 will have a strong dependence on the stability of the timing inputs. The most sensitive inputs are the HCCD and the CDS timing inputs. The evaluation board uses one PGA (U8) to hold all of the counters and to generate the CDS timing. This is not the optimum arrangement. Though gray code counters were used, some fixed pattern column noise can be seen in the image from the counters inside U8. The counters inside U8 cause small disturbances of the HCCD and CDS timing. One solution to eliminate this noise source is to separate the counters and CDS pulse generation into two separate PGA's. One PGA would contain all of the counters for the rows and columns, and send a HCCD gating signal to a second PGA. The second PGA would output the HCCD clock as well as form the CDS timing pulses from the multi-tap delay line U10. This second PGA would contain no counters.

### **Output channel**

The output circuit is identical to section 0. The two op-amps U5A and U5B present an inverted signal to the ADC U4. The offset circuit will maintain the digital output of U4 at 4080 when the image sensor is in the dark. The output of U4 will be zero when the image sensor is saturated with light. The digital data is inverted by swapping the high and low outputs of the differential line drivers on the output connector.

### **Automatic offset**

U12 is used to control the automatic offset circuit. U8 sends a signal to U12 on the line BLKLEV when the output of the analog to digital converter corresponds to the center 10 columns of the KAI1020 dark reference. When U12 receives the signal from U8, U12 compares the outputs of the A/D converters to the number 4080. If the output is above or below 4080, U12 enables the buffers U22 and U23 and sets their inputs to cause the integrators U13A and U13B to raise or lower the offset voltages.

A separate PGA (U12) is used to monitor the output of the A/D converters. This function should not be combined with U8 into one PGA. If only one PGA is used then the digital data will cause noise in the timing outputs to the image sensor. This is especially true when the A/D outputs are near a major bit boundary, such as 2048 or 1024. At these bit boundaries there are a large number of bits changing value that would disturb the stability of the HCCD and CDS clocking.

The automatic offset updates the offset every line. This does cause some noise in the image because the offset changes slightly each line time. An improved offset circuit would measure the offset error along the entire column and then correct the offset voltage once per frame.

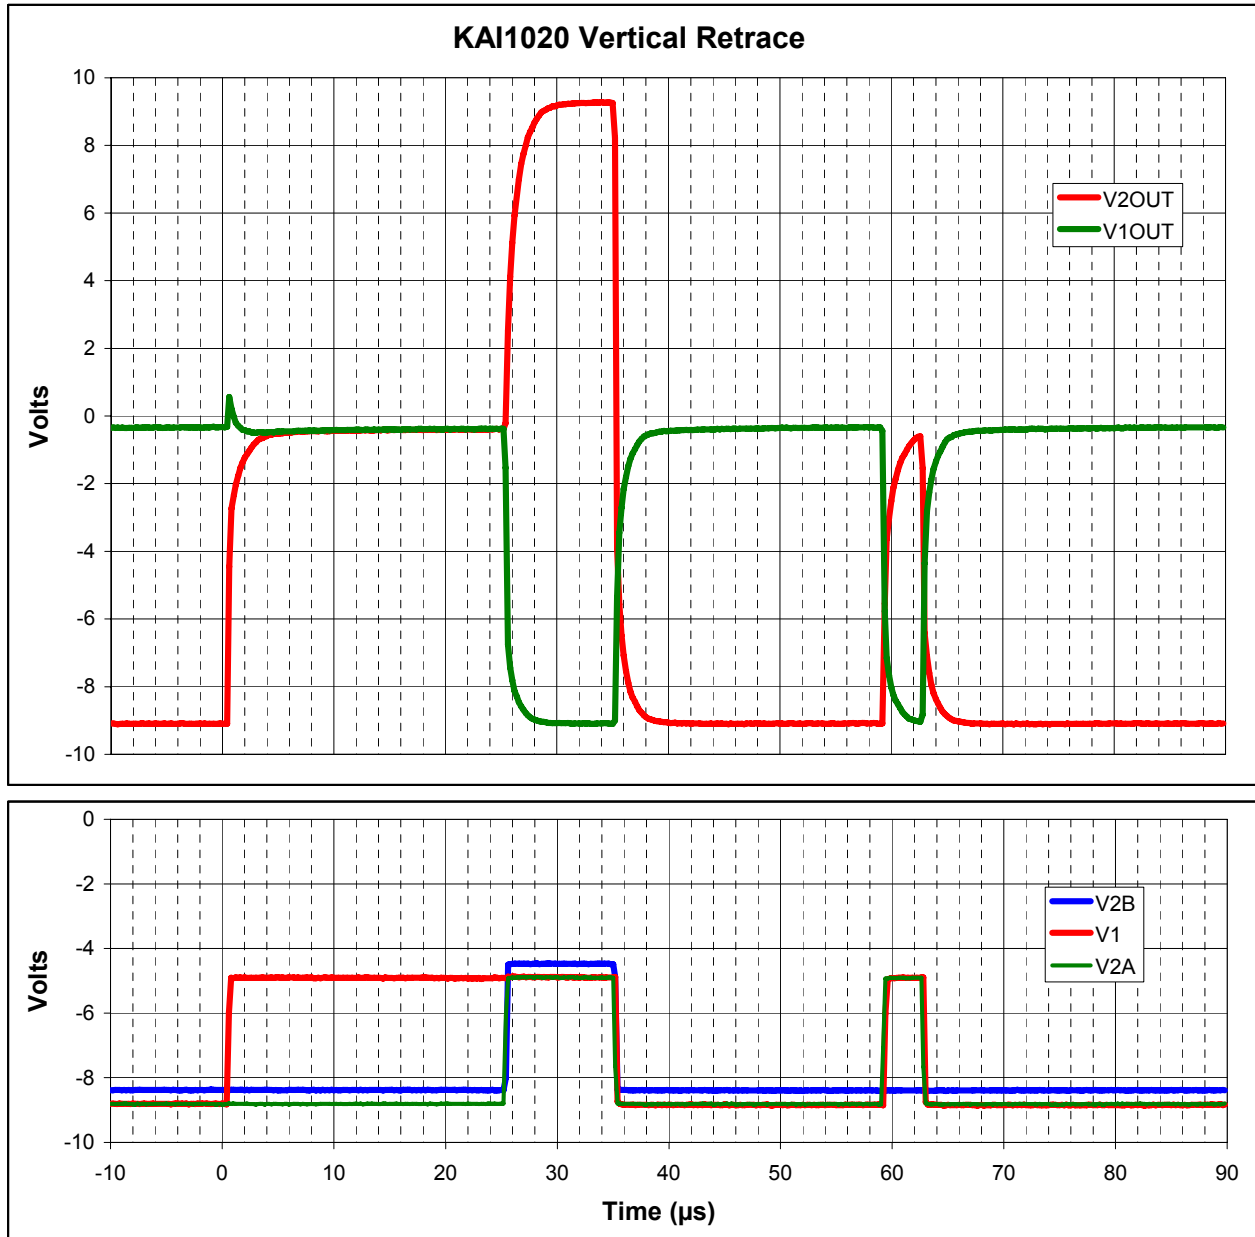

## OSCILLOSCOPE TRACES

This section contains oscilloscope traces of signals measured on the KAI1020 pins. Some of the timing signals are not 0 to 5V because the KAI1020 has level shifted the signals. All signals were measured on the KAI1020 evaluation board.

Horizontal Retrace

## STORAGE AND HANDLING

### ESD

1. This device contains limited protection against Electrostatic Discharge (ESD). CCD image sensors can be damaged by electrostatic discharge. Failure to do so may alter device performance and reliability.
2. Devices should be handled in accordance with strict ESD procedures for Class 0 (<250V per JESD22 Human Body Model test), or Class A (<200V JESD22 Machine Model test) devices.
3. Devices are shipped in static-safe containers and should only be handled at static-safe workstations.
4. See Application Note MTD/PS-0224 “Electrostatic Discharge Control for Image Sensors” for proper handling and grounding procedures. This application note also contains recommendations for workplace modifications for the minimization of electrostatic discharge.
5. Store devices in containers made of electro-conductive materials.

### COVER GLASS CARE AND CLEANLINESS

1. The cover glass is highly susceptible to particles and other contamination. Perform all assembly operations in a clean environment.
2. Touching the cover glass must be avoided
3. Improper cleaning of the cover glass may damage these devices. Refer to Application Note MTD/PS-0237 “Cover Glass Cleaning for Image Sensors”

### ENVIRONMENTAL EXPOSURE

1. Do not expose to strong sun light for long periods of time. The color filters and/or microlenses may become discolored. Long time exposures to a static high contrast scene should be avoided. The image sensor may become discolored and localized changes in response may occur from color filter/microlens aging.
2. Exposure to temperatures exceeding the absolute maximum levels should be avoided for storage and operation. Failure to do so may alter device performance and reliability.
3. Avoid sudden temperature changes.
4. Exposure to excessive humidity will affect device characteristics and should be avoided. Failure to do so may alter device performance and reliability.
5. Avoid storage of the product in the presence of dust or corrosive agents or gases.

Long-term storage should be avoided. Deterioration of lead solderability may occur. It is advised that the solderability of the device leads be re-inspected after an extended period of storage, over one year.

## QUALITY ASSURANCE AND RELIABILITY

### QUALITY STRATEGY

All image sensors will conform to the specifications stated in this document. This will be accomplished through a combination of statistical process control and inspection at key points of the production process. Typical specification limits are not guaranteed but provided as a design target. For further information refer to ISS Application Note MTD/PS-0292, Quality and Reliability.

### REPLACEMENT

All devices are warranted against failure in accordance with the terms of Terms of Sale. This does not include failure due to mechanical and electrical causes defined as the liability of the customer below.

### LIABILITY OF THE SUPPLIER:

A reject is defined as an image sensor that does not meet all of the specifications in this document upon receipt by the customer.

### LIABILITY OF THE CUSTOMER

Damage from mechanical (scratches or breakage), electrostatic discharge (ESD) damage, or other electrical misuse of the device beyond the stated absolute maximum ratings, which occurred after receipt of the sensor by the customer, shall be the responsibility of the customer.

Kodak reserves the right to change any information contained herein without notice. All information furnished by Kodak is believed to be accurate.

## WARNING: LIFE SUPPORT APPLICATIONS POLICY

Kodak image sensors are not authorized for and should not be used within Life Support Systems without the specific written consent of the Eastman Kodak Company. Product warranty is limited to replacement of defective components and does not cover injury or property or other consequential damages.

### RELIABILITY

Information concerning the quality assurance and reliability testing procedures and results are available from the Image Sensor Solutions and can be supplied upon request. For further information refer to ISS Application Note MTD/PS-0292, Quality and Reliability.

### TEST DATA RETENTION

Image sensors shall have an identifying number traceable to a test data file. Test data shall be kept for a period of 2 years after date of delivery.

### MECHANICAL

The device assembly drawing is provided as a reference. The device will conform to the published package tolerances.
